Versions to run project on:
Flutter: v3.7.12
Dart: v2.19.6

How The Project Works And Where Files Are

The “landing screen” file in the “screens” folder runs upon first opening the website. The landing screen works through an “on press” call which runs a function leading to another page (flie) upon a user’s click.

Flashcards>lib>screens
Has all the files for the different pages

The notifications and calendar functionality pull from the firebase database and send emails on a set date. Firebase > cloudFunctions deals with the notifications.

In the folder “utils” there is a file called algo.dart which has the algorithm that handles the space repetition for revision reminders.

“Widget” folder is where the pages are actually built.

All tests are in the actions tab on github
Integration test folder > integrationTests.dart
The test bot was very buggy so probably still doesn’t work; might be better to start the test files from scratch.

Need to install packages if we want to start working on the mobile app

Read > docs > 2021(2023) has useful information on the foundations of the code base

Personal Advice from Dhillon:

- Step through the code with breakpoints to understand the code better
- We’ll need to focus on the “calendar” folder for most of the features the client has requested us to implement.
- Testing in flutter is difficult
- Try building a smaller scale app in Dart using a YT tutorial before working on the project
- Paste code into ChatGPT and ask it to explain if you still feel stuck
